
Introduction to Computational Physics SS2020

Lecturers: Rainer Spurzem & Ralf Klessen

Tutors: Mischa Breuhaus, Li-Hsin Chen, Ismael Pessa Gutierrez,
Da Eun Kang, Giancarlo Mattia, Toni Peter

Exercise 10 from June 24, 2020

Return before noon of July 3, 2020

1 Random Numbers – Rolling Dice

- Write a simple portable random number generator, using linear congruences

$$I_{j+1} = aI_j + c \pmod{m}.$$

It produces homogeneously distributed numbers between 0 and $m - 1$; we can normalize them by $r_j = I_j/(m - 1)$ to get homogeneously distributed real numbers between 0 and 1. Choose e.g. $a = 106$, $m = 6075$, $c = 1283$, from Numerical Recipe's recommendation. Experiment with other values.

- A simple way to check 'by eye' that your random number generator produces really homogeneously distributed numbers is to create two sequences with different initial values I_0 and J_0 , normalize both sequences between 0 and 1 as above ($r_0 = I_0/(m - 1)$, $s_0 = J_0/(m - 1)$, $0 \leq r_i, s_i \leq 1$), and plot all pairs (r_i, s_i) in the quadrat $0 \leq r \leq 1$, $0 \leq s \leq 1$. The eye is quite sensitive to see a good distribution.
- You can see the deterministic character of this random number sequence by plotting I_{j+1} against I_j .
- Repeat the previous steps by using the routine `ran2` of Numerical Recipes (will be provided).

Simulate rolling dice with your random number generator, i.e. obtain uniformly distributed random integer numbers between 0 and 6. Roll the dice ten times and sum up the result. The possible numbers lie between 10 and 60. Plot the distribution of these numbers for 10.000 experiments (of 10 dice each). The theoretical expectationi for this distribution is given by the central limit theorem.

2 Probability distribution functions (Homework)

Consider a probability distribution function $p(x)$ given in the domain $[0, a]$ by

$$p(x) = bx \quad (2.1)$$

Assume that $\{r_i\}$ is a random set of numbers, distributed uniformly between 0 and 1.

- Give the proper value of b as a function of a such that the probability distribution function is properly normalized.
- Use the rejection method to make a set $\{x_i\}$ that obeys Eq.(2.1) for $a = 0.5$.
- Make a histogram of the resulting numbers and check that the histogram indeed follows Eq.(2.1), i.e. overplot Eq.(2.1). Experiment with the size of the set (the number of random numbers drawn), to find out how large you have to make it to get (by eye) a reasonable fit.

(10 points)

3 Determine π with random numbers RN (Homework)

Compute the number π using a rejection method with the function $f(x) = \sqrt{1 - x^2}$, for $0 \leq x \leq 1$. Hint: It is enough to use only one quadrant $x, f(x) > 0$. Vary the number of RNs widely (orders of magnitude) and plot the accuracy of the result as a function of the number of RNs. Use logarithmic variables for the plot.
